NMR SPECTROSCOPY

^1H NMR SPECTROSCOPY

Метод **ядерного магнитного резонанса (ЯМР)** основан на взаимодействии внешнего магнитного поля основан на взаимодействии внешнего магнитного поля с ядрами) основан на взаимодействии внешнего магнитного поля с ядрами, имеющими магнитный момент, т. е. для ядер с ненулевым спином. К ним относятся ^1H , ^{13}C , ^{15}N , ^{31}P и другие. Спектроскопия ЯМР на ядрах ^1H в настоящее время наиболее развита и получила название протонный магнитный резонанс (ПМР).

Ядролық магниттік резонанс (ЯМР) сыртқы магниттік өрістің магнитті моменті бар ядролармен өзара әрекетіне негізделген. Оларға ^1H , ^{13}C , ^{15}N , ^{31}P және басқалар жатады. Ядросында ^1H бар спектроскопия қазір жақсы дамыған және ол протонды магнитті резонанс (ПМР) деп аталады.

Сабақтың мақсаты:
Ядролық магнитті резонанс
әдісімен танысу
ЯМР қарапайым
спектрлерімен танысу

Тілдік терминология

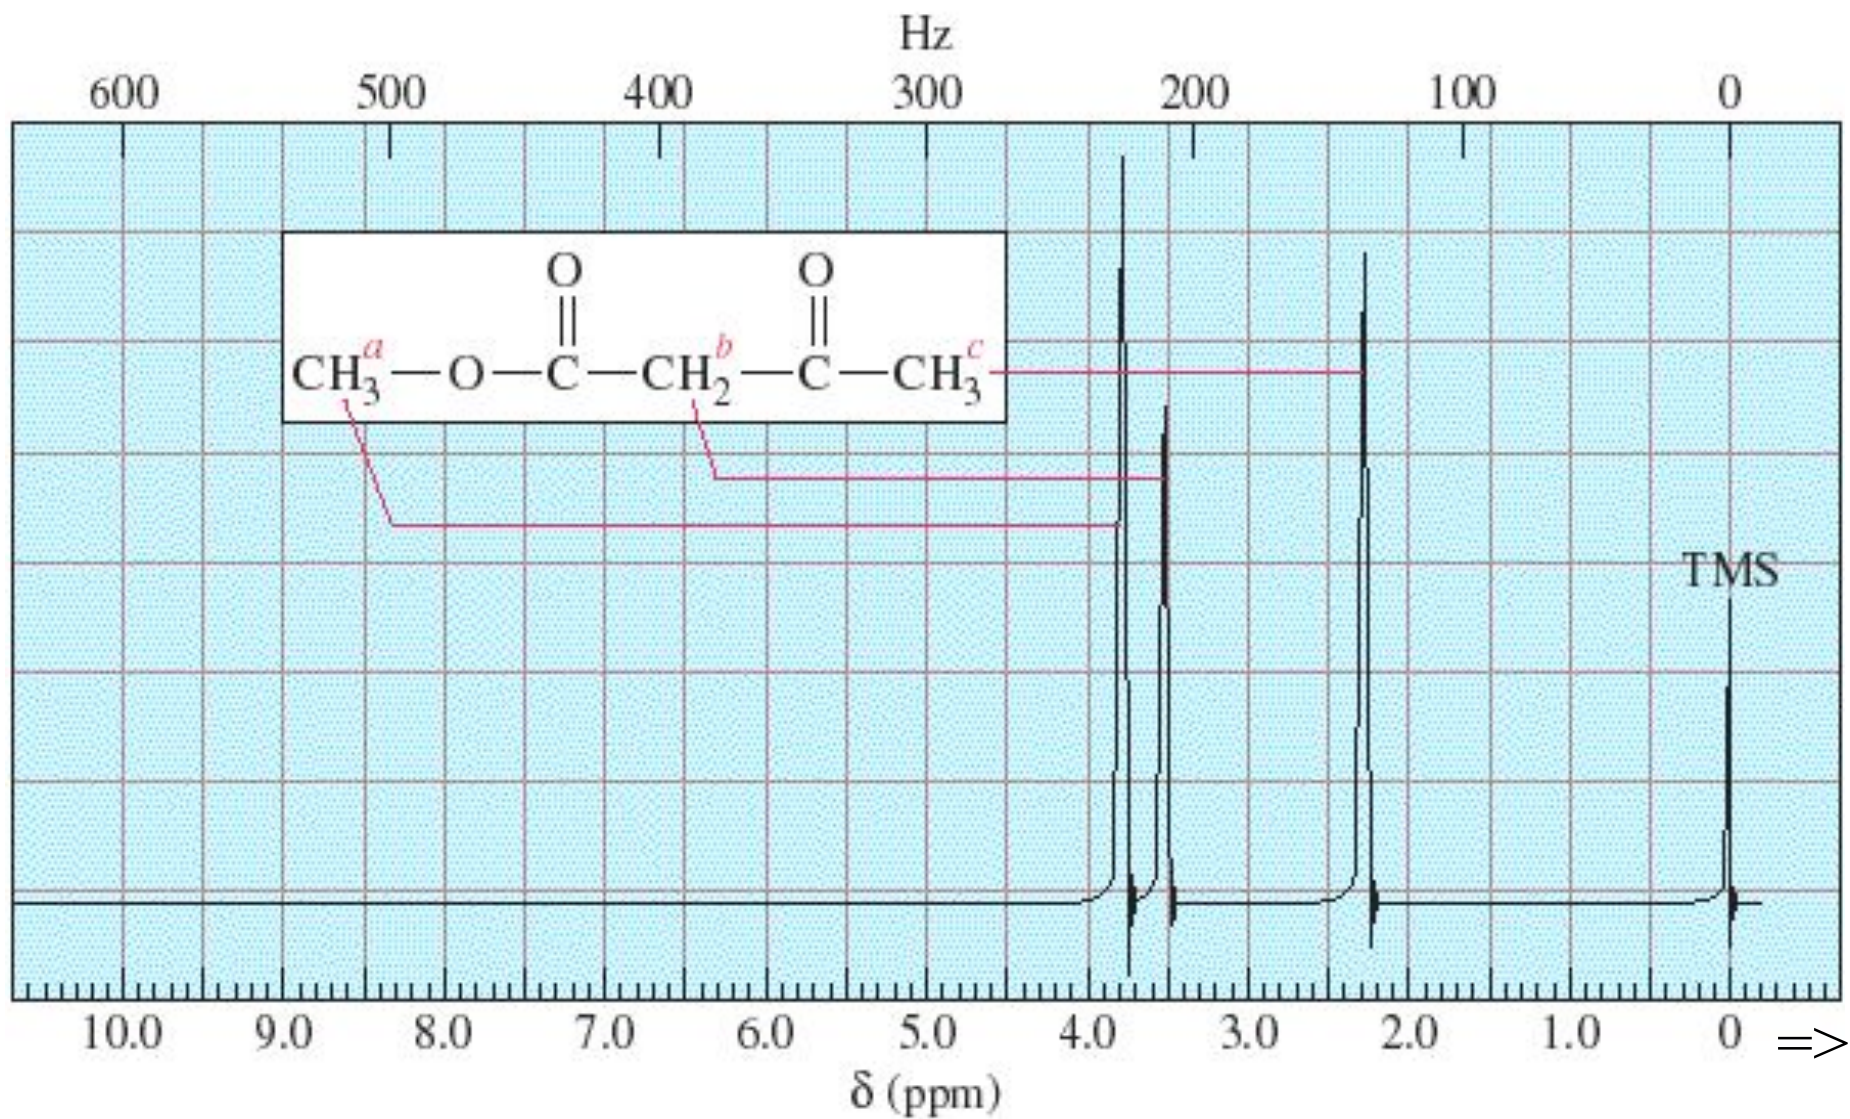

Ядролық магнитті резонанс
-magnetic nuclear resonance-
ядерно магнитный резонанс

SOLVENTS & CALIBRATION

- Samples are dissolved in solvents free of ^1H atoms, e.g. CCl_4 , CDCl_3 .
- A small amount of TMS (tetramethylsilane) is added to calibrate the spectrum.
- It is used because:
 - its signal is away from all the others
 - it only gives one signal
 - it is non-toxic
 - it is inert
 - it has a low boiling point so is easy to remove

No. of Signals = No. of Environments

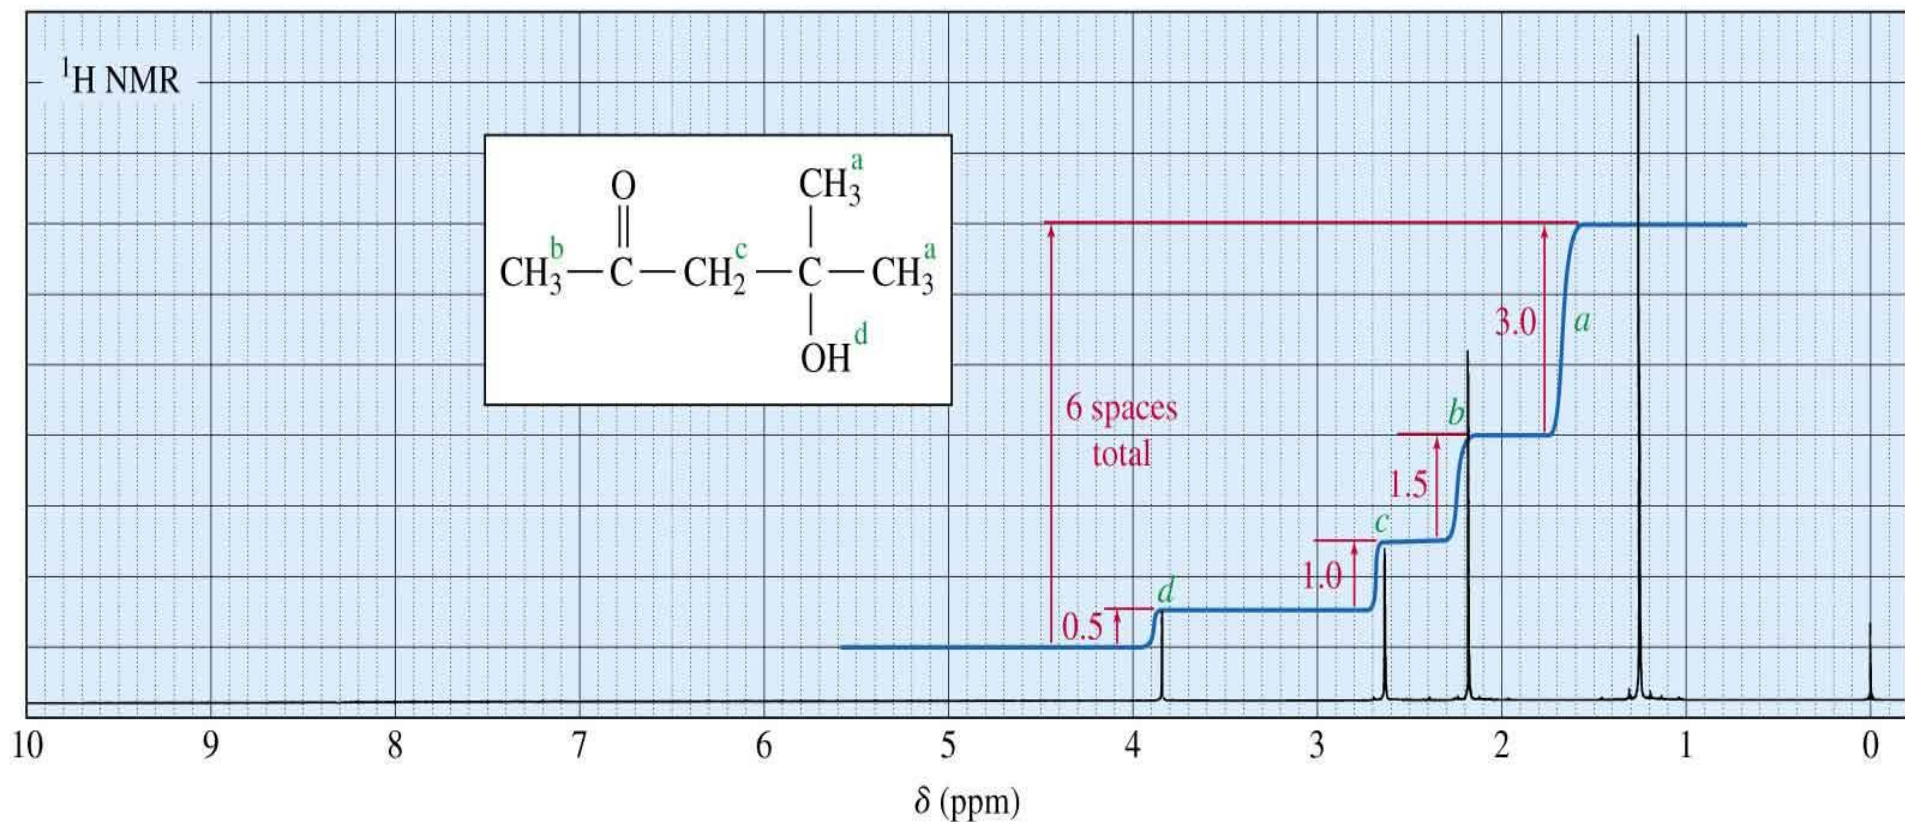

Intensity of Signals \propto Number of H

- The area under each peak is proportional to the number of protons.
- Площадь под каждым пиком пропорциональна числу протонов
- Shown by integral trace. Показанный на интегральной кривой.

How Many Hydrogens?

When the molecular formula is known, each integral rise can be assigned to a particular number of hydrogens.

EQUIVALENT H'S

- In a spectrum, there is one signal for each set of equivalent H atoms. В спектре , есть один сигнал для каждого набора эквивалентных атомов H .
- The intensity of each signal being proportional to the number of equivalent H atoms it represents.
- Интенсивность каждого сигнала пропорциональна количеству эквивалентных атомов H он представляет.

2 sets of equivalent H's: ratio 6:2 (3:1)

4 sets of equivalent H's: ratio 3:1:2:3

5 sets of equivalent H's: ratio 3:1:2:2:3

4 sets of equivalent H's: ratio 6:1:2:3

For each of the following compounds, predict the number of signals and the relative intensity of the signals.

Splitting for 3-methylpropan-2-one

Number of H's next door +1

But you don't couple to

- H's that are equivalent
- H's on O's

Hydroxyl Proton

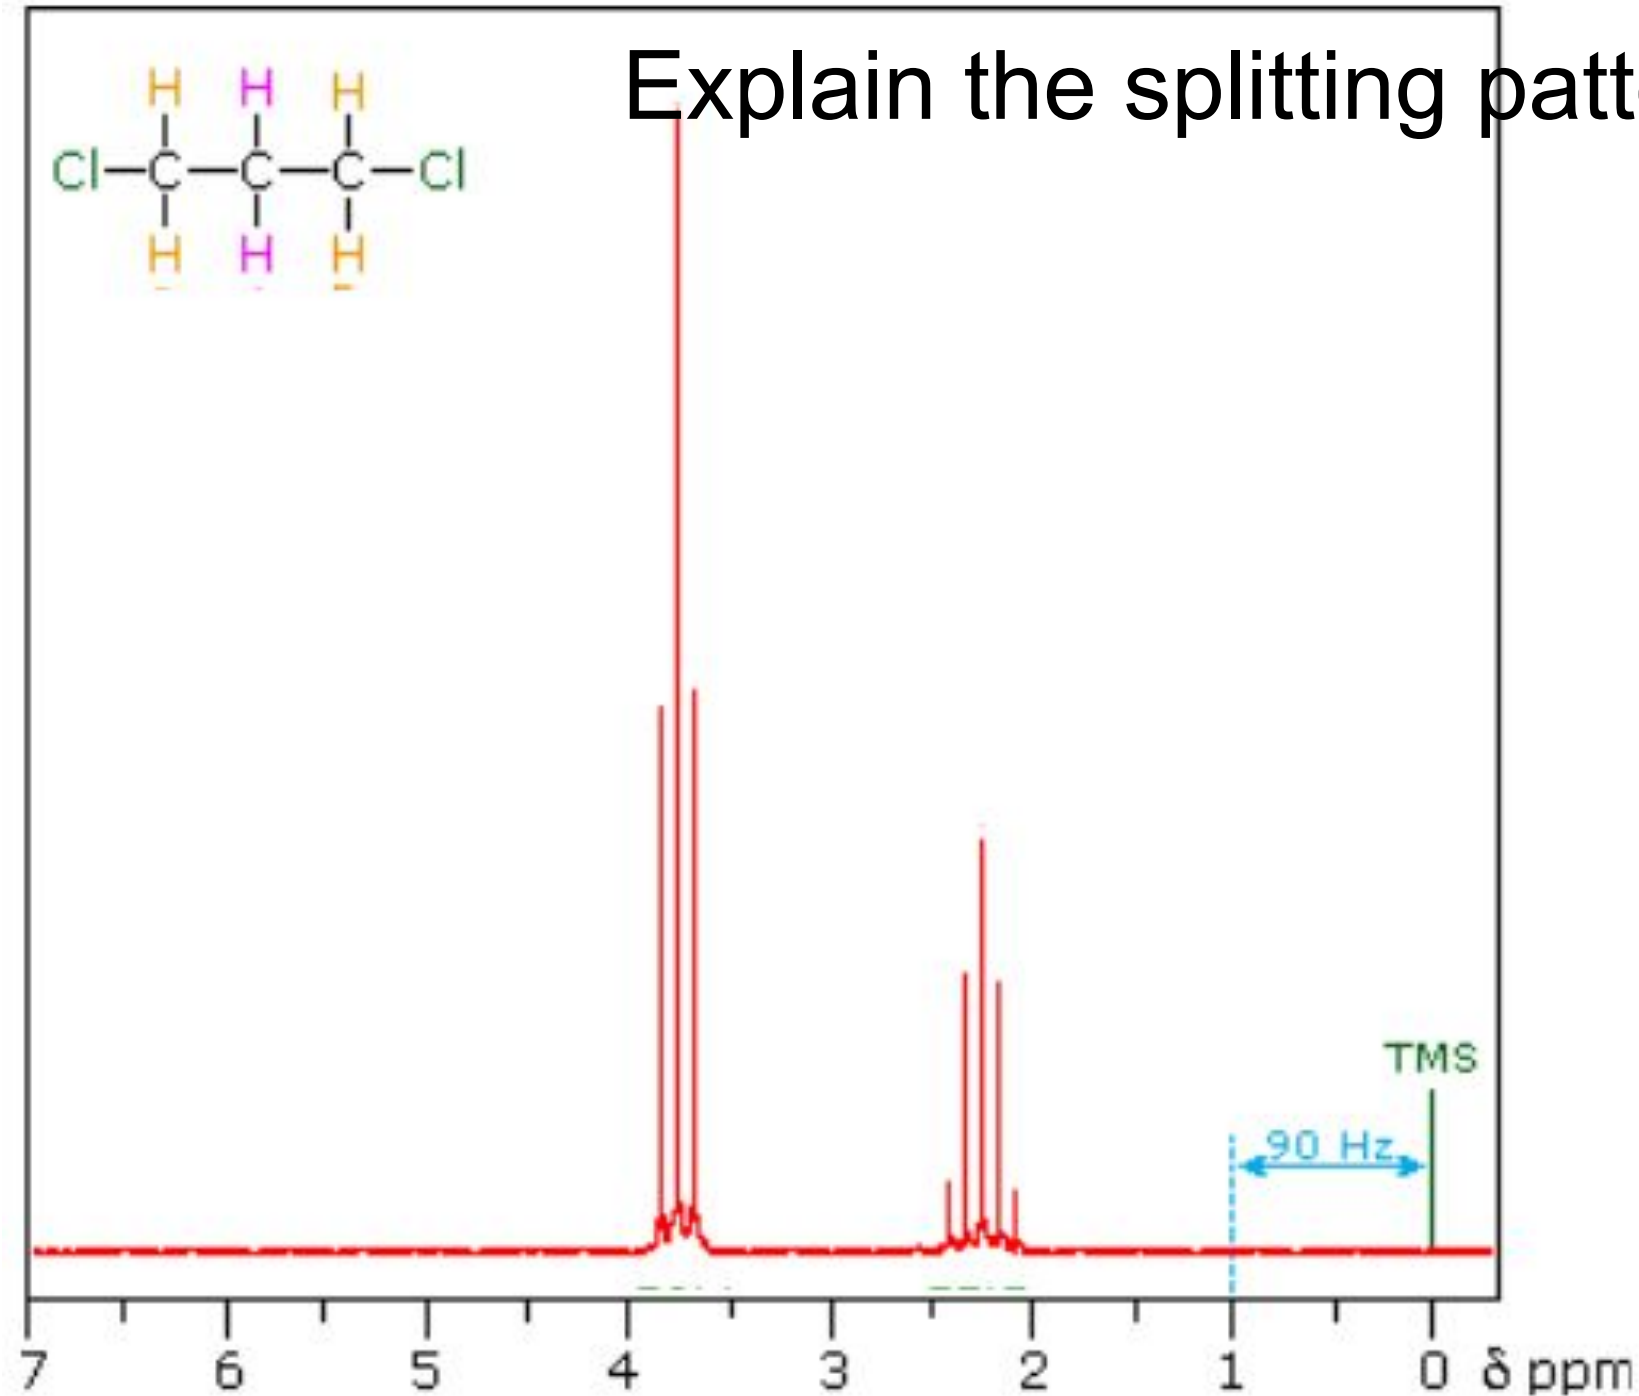

Ethanol with a small amount of acidic or basic impurities will not show splitting.

Explain the splitting patterns

Explain the splitting patterns

methyl propanoate

Explain the splitting patterns

methyl propanoate

Hydroxyl Proton

Arises because the H on the OH, rapidly exchanges with protons on other molecules (such as water or acids) and is not attached to any particular oxygen long enough to register a splitting signal.

**OH hydrogens are
always seen as a singlet
... there is no splitting**

**This is a quartet despite
the fact that there are 4
H's on adjacent atoms -
the H on the OH doesn't
couple**

Identifying the O-H or N-H Peak

- Chemical shift will depend on concentration and solvent.
- To verify that a particular peak is due to O-H or N-H, shake the sample with D_2O
- Deuterium will exchange with the O-H or N-H protons.
- On a second NMR spectrum the peak will be absent, or much less intense.

before shaking with D_2O

after shaking with D_2O

H atoms attached to the N in amines also interchange with deuterium

SUMMARY

Number of signals how many different sets of equivalent H atoms there are

Position of signals information about chemical environment of H atom

Relative intensities gives ratio of H atoms for peaks

Splitting how many H atoms on adjacent C atoms

For each of the following compounds, predict the number of signals, the relative intensity of the signals, and the multiplicity of each signal.

^{13}C NMR SPECTROSCOPY

KEY POINTS

- ^{13}C NMR spectra are often simpler than ^1H NMR spectra.
- They give a lot of valuable information about the chemical environment of C atoms (e.g. the difference between C atoms in $\text{C}=\text{O}$, $\text{C}-\text{N}$, $\text{C}\equiv\text{N}$, $\text{C}-\text{C}$, $\text{C}=\text{C}$, etc.).
- There is one signal for each set of equivalent C atoms.
- There is no coupling (unlike ^1H NMR).
- The size of signal is not relative to the number of equivalent C atoms (unlike H atoms in ^1H NMR).
- As in ^1H NMR, the chemical shift (δ) is measured relative to TMS.
- Although deuterated solvents are usually used, there will be a signal for any C atoms in the solvent.

Example 1 - butanone
