# X-Ray Machine

Chapter 1/ white & pharoah Dr yazdanpanah OMFR

# X-Ray Machine

X-ray machines produce x rays that pass through a patient's tissues and strike a digital receptor or film to make a radiographic image.

- primary components of an x-ray machine :
- x-ray tube
- 2. power supply

The x-ray tube is positioned within the tube head

- An electrical insulating material, usually oil, surrounds the tube and transformers.
- Often, the tube is tecessed within the tube head to improve the quality of the radiographic image

# X-Ray Machine

■Tube head

□Arm

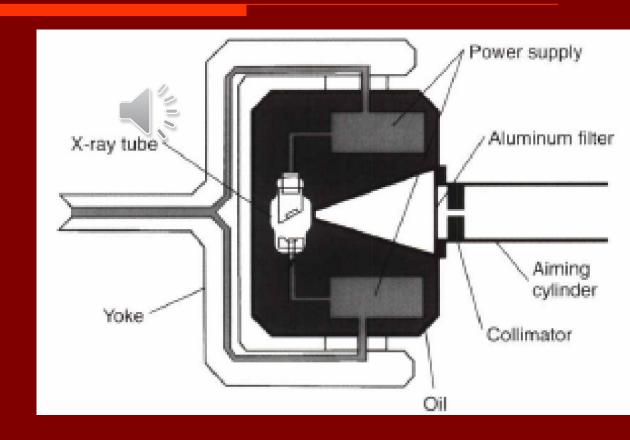

□Control Panel

#### Tube Head

■X-Ray Tube

■Power Supply

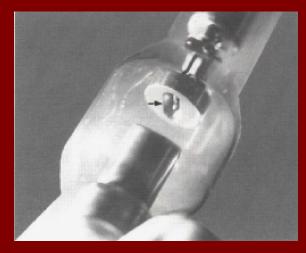

#### Power supply

- Heat the cathode filament to generate electrons.
- High potential difference accelerate electrons from calfode to the focal spot on the anode.

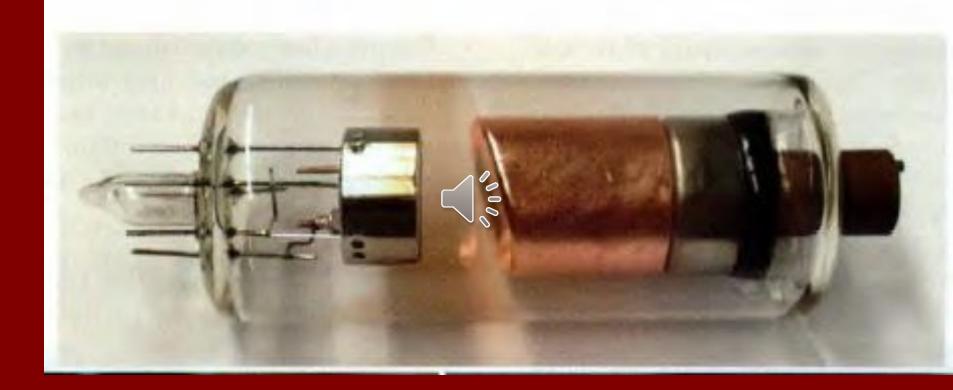

#### Cathode

- Filament:
  - tungsten + 1% thorium
- Focusing cup
  - molybdenum

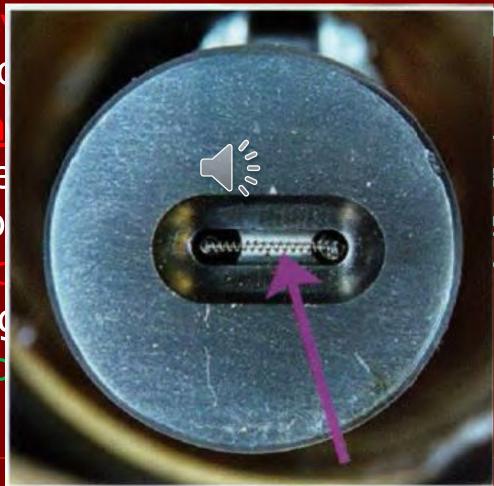

## Filament

#### Focusing cup

## X-Ray Tube

Glass envelope

### X-Ray Tube

- Glass envelope
  - Evacuated to prevent collision of the fast-moving electrons with gas
- molecules, which would significantly reduce their speed.
- The vacuum also prevents oxidation, or "burnout," of the filament.

#### Anode

Tungs Glass envelope Vacuum □ Coppe Copper stem )de (+)

#### Anode

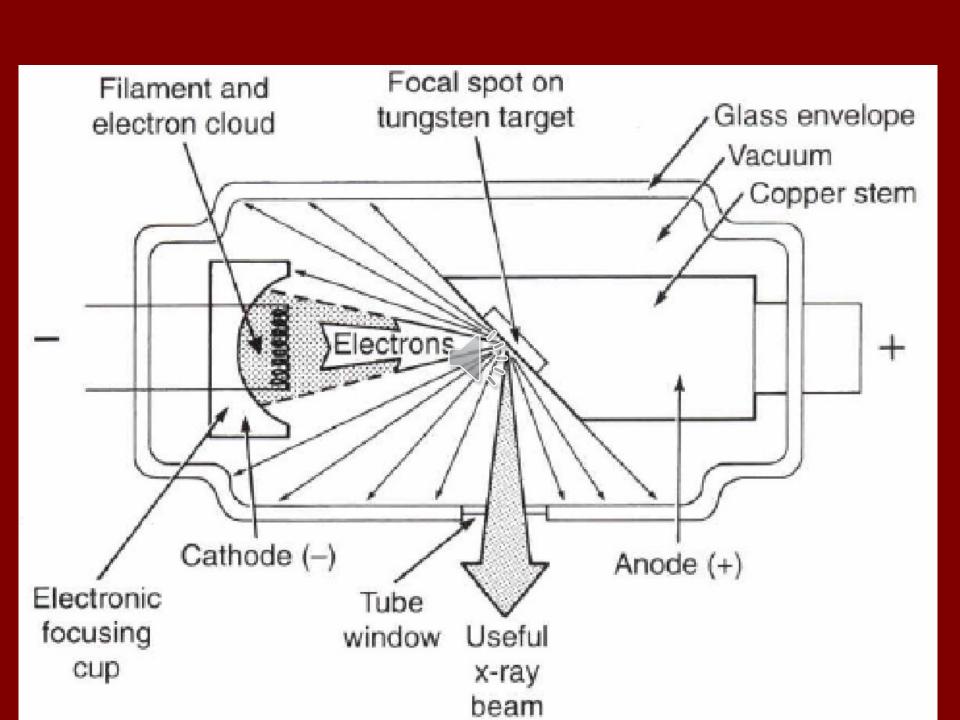

- Purpose of target:
- □ Conversion of energy to X-ray is inefficient

#### Ideal Target

- High atomic number(74)
- High melting point(3422 °C)
- □ High thermal conductivity(173 W, m<sup>-1</sup>,K<sup>-1</sup>)
- Low vapor pressure

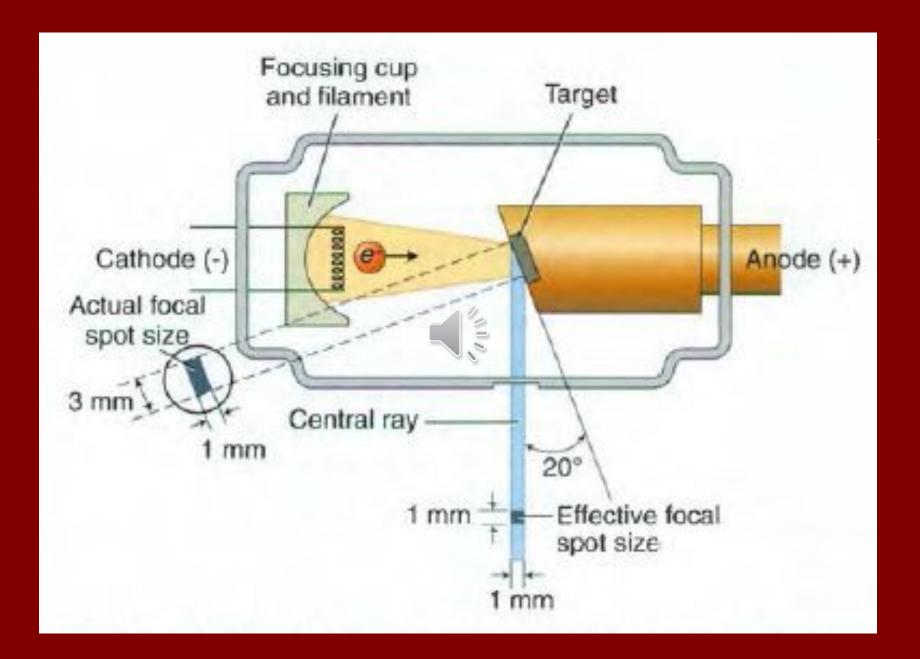

### Focal Spot

The area on the target to which the focusing cup directs the electrons and from which x rays are produced

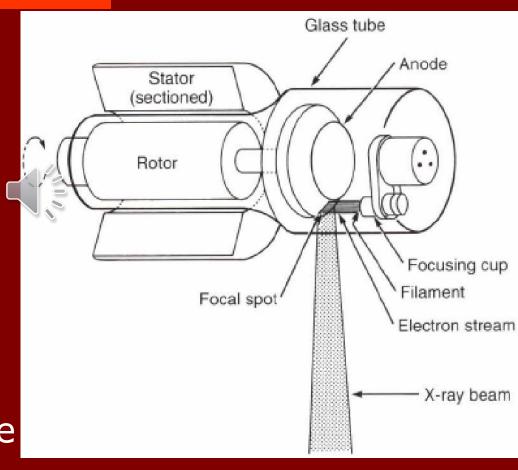

### Focal Spot

- Size: is important to image quality
  - sharpness
  - heat:1.stationary anode 2.rotating anode
- Angle of target:target is inclined 20 degrees to the central ray
  - effective focal spot: 1 x 1 mm
  - actual focal spot: 1 x 3 mm

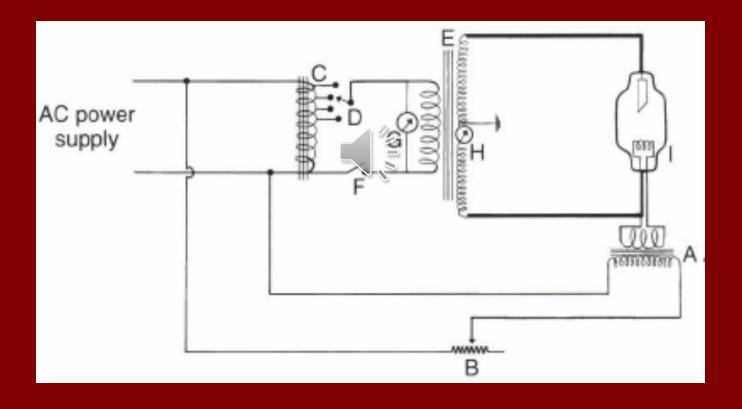

# Methods of dissipating the heat : from focal spot

- Anode
- Angle of target
- Copper stem
- Insulating oil
- Rotating anode:
  - focal track
  - CT
  - cephalometic & cone-beam machine

#### Power supply

- Primary functions:
- 1. Low voltage: emit electrons
- 2. High voltage: accelerate electrons
- Head of x-ray machine:
  - x-ray tube
  - 2 transformers
  - insulating oil

#### **Tube Current**

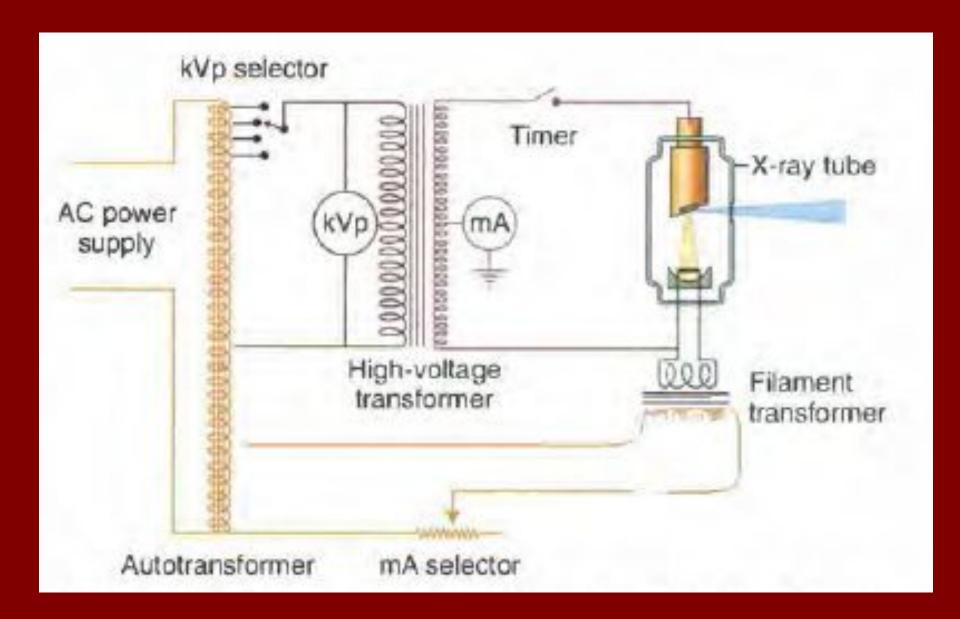

Filament step-down transformer (filament transformer)(10v)

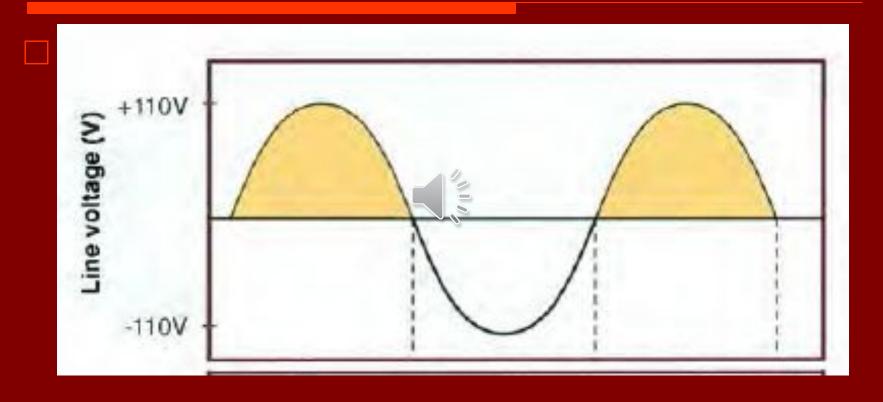

- mA selector or filament current control:
  - actually tube current

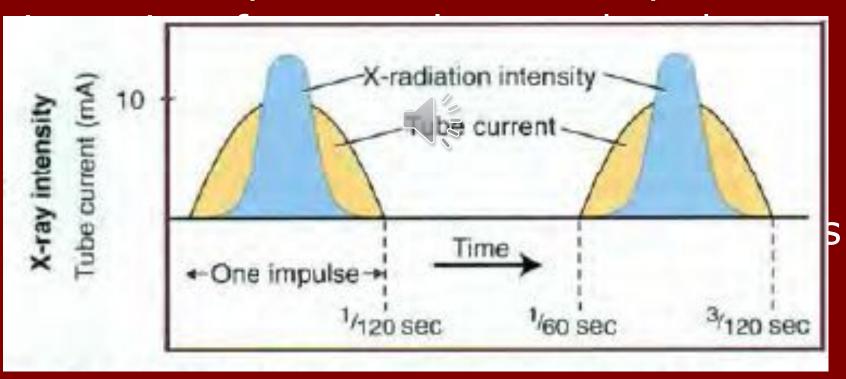

- When the hot filament releases electrons, it creates a cloud of electrons around the filament, a negative space charge.
- This negative space charge imbedes the further release of electrons. The higher the voltage, the greater the removal of the electrons from the space charge, and the greater the tube current.

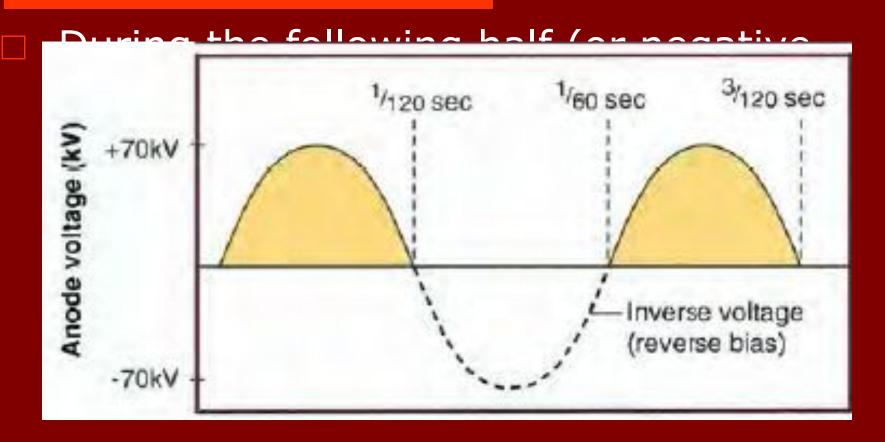

- Why High voltage?
- Autotransformer:
  - The actual voltage use on an x-ray machine is adjusted with the autotransformer

Voltage ↑ speed of electron ↑

- Self-rectified or Half-wave rectified:
- The alternating high voltage is applied directly across the x-ray tube, limits x-ray production a half the AC cycle
- Conventional dental x-ray machines are self-rectified

- Replace the conventional 60-cycle AC, half-wave rectified power supply with a full-wave rectified, high-frequency power supply
- Higher mean energy
- images have a longer contrast scale
- The patient receives a lower dose

Intraoral, Panoramic, and Cephalometric machines operate between 50 and 90 kVp, whereas cone-beam complified tomographic machines operate at 90 to 120 kVp

#### Timer

- Duration of x-ray exposure/ into the high-voltage circuit
- □ Length of high-voltage
- To minimize filament damage

Tube Rating: longest exposure time

HU = (kVp x mA) x seconds

The heat storage capacity for anodes of dental diagnostic tubes is approximately 20 kHU

- Duty Cycle: frequency of exposures
- anode size
- cooling methods

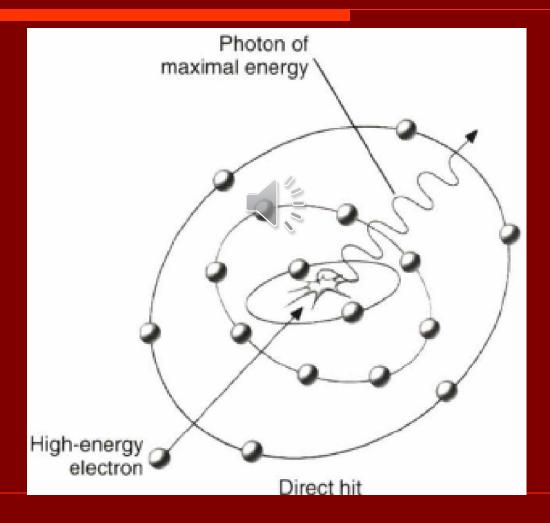

# Production of X-Rays

Most energy : Heat

# Bremsstrahlung Radiation (برم اشترالانگ)

- The sudden stopping or slowing of high-speed electrons by tungsten nuclei
- "breaking radiation
- Primary source

# Electrons from the filament directly hit the nucleus of a target atom

#### Bremsstrahlung X-ray Production Maximum energy

Clip slide

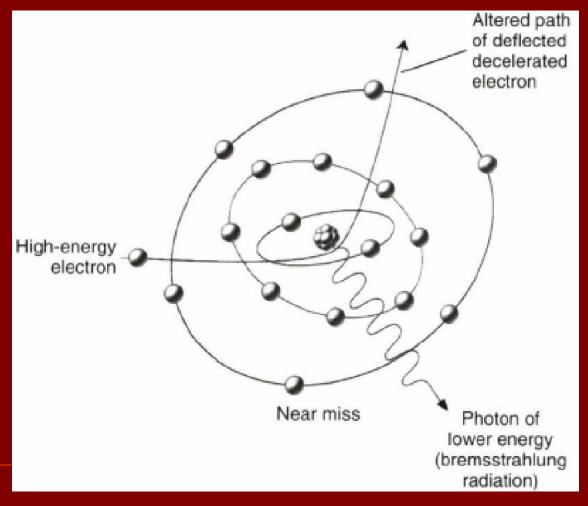

High-speed electron from filament enters tungsten atom and strikes target, losing all its energy and disappearing

The x-ray produced has energy equal to the energy of the high-speed electron; this is the maximum energy possible

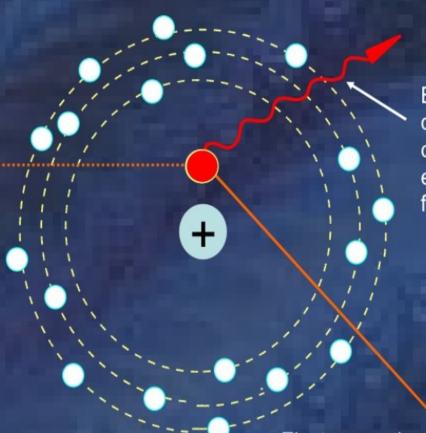

High-speed electrons pass by tungsten nuclei with near or wide misses(proportional to the square of the atomic number of the

target)

0

#### Bremsstrahlung X-ray Production

High-speed

electron from

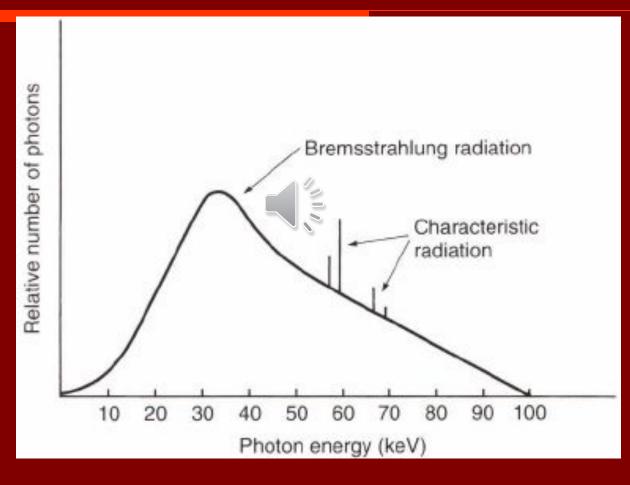

filament enters

tungsten atom

Electron slowed down by positive charge of nucelus; energy released in form of x-ray

Electron continues on in different direction to interact with other atoms until all of its energy is lost

# Continuous spectrum of energy

### Bremsstrahlung Radiation

The continuously varying voltage difference between the target and filament causes the electrons striking the target to have varying levels of kinetic energy.

# Bremsstrahlung Radiation

The bombarding electrons pass at varying distances around tungsten nuclei and are thus deflected to varying extents. As a result, they give up varying amounts of energy in the form of bremsstrahlung photons.

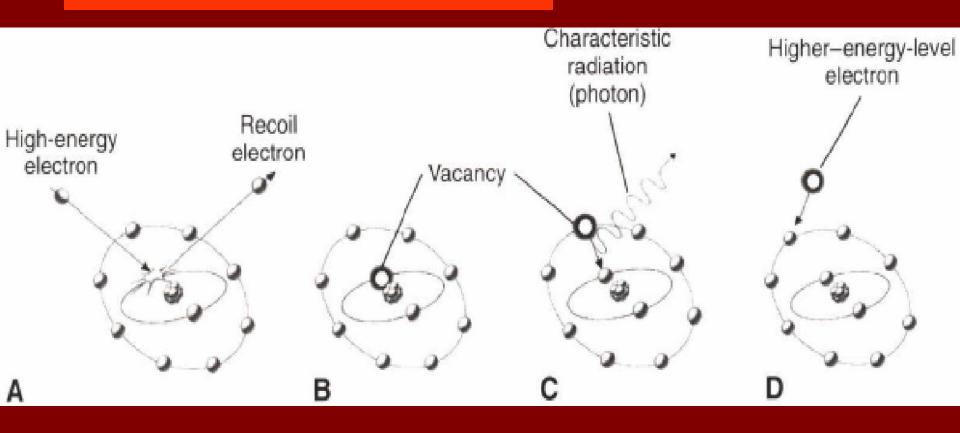

# Bremsstrahlung Radiation

Most electrons participate in the target before losing all their kinetic energy. As a consequence, an electron carries differing amounts of energy after successive interactions with tungsten nuclei

#### Characteristic Radiation

- Characteristic radiation contributes only a small fraction of the photons in an x-ray beam
- An incident electron ejects an inner electron from the tungsten target
- When the outer orbital electron replaces the displaced electron, a photon is emitted

#### Characteristic Radiation

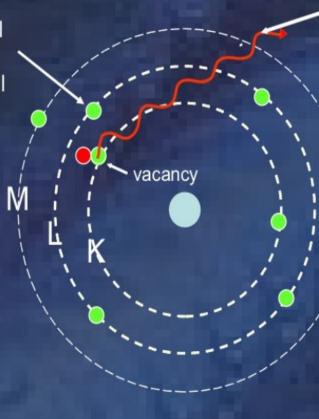

### Characteristic X-ray Production

Electron in L-shell drops down to fill vacancy in K-shell

High-speed electron with at least 70 keV of energy (must be more than the binding energy of k-shell Tungsten atom) strikes electron in the K shell, knocking it out of its orbit

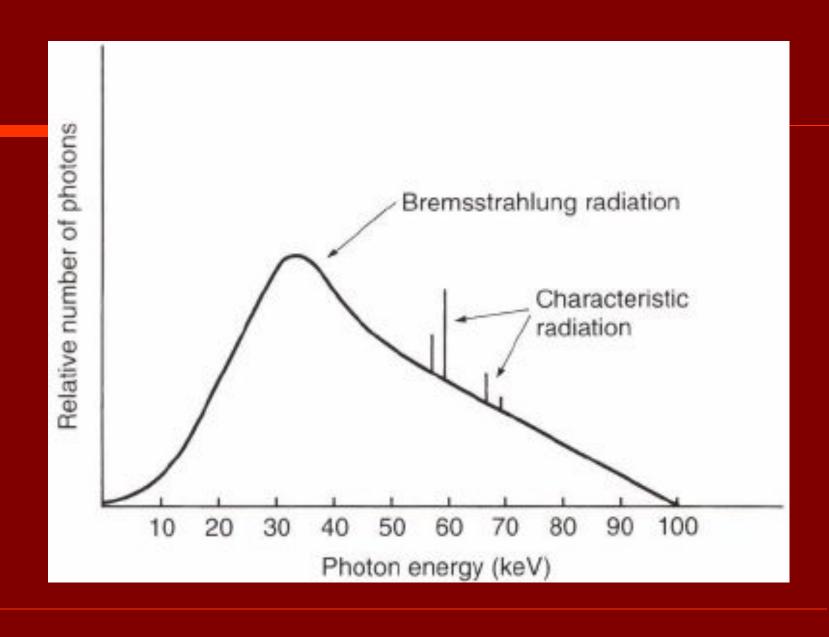

Ejected electron leaves atom

X-ray with 59
keV of energy
produced. 70
(binding energy
of K-shell
electron) minus
11 (binding
energy of Lshell electron) =
59.

Recoil electron (with very little energy) exits atom

- Small fraction
- Discrete spectrum
- Difference of energy levels of electron orbitals
- Characteristic of target atoms

The Orinoco River near the Esmeralda (Amazon Rain Forest), Amazonas region, Venezuela (N 3\*10'W 65\*33')
