# Assumption of Homoscedasticity

## Homoscedasticity (also referred to as homogeneity of variance) (also referred to as uniformity of variance)

Transformations

Assumption of normality script

Practice problems

# Assumption of Homoscedasticity

- Homoscedasticity refers to the assumption that that the dependent variable exhibits similar amounts of variance across the range of values for an independent variable.
  - While it applies to independent variables at all three measurement levels, the methods that we will use to evaluation homoscedasticity requires that the independent variable be non-metric (nominal or ordinal) and the dependent variable be metric (ordinal or interval). When both variables are metric, the assumption is evaluated as part of the residual analysis in multiple regression.

## Evaluating homoscedasticity

- Homoscedasticity is evaluated for pairs of variables.
- There are both graphical and statistical methods for evaluating homoscedasticity.
- The graphical method is called a boxplot.

3

The statistical method is the Levene statistic which SPSS computes for the test of homogeneity of variances.

## Transformations

4

When the assumption of homoscedasticity is not supported, we can transform the dependent variable variable and test it for homoscedasticity. If the transformed variable demonstrates homoscedasticity, we can substitute it in our analysis.

- We use the sample three common transformations that we used for normality: the logarithmic transformation, the square root transformation, and the inverse transformation.
- All of these change the measuring scale on the horizontal axis of a histogram to produce a transformed variable that is mathematically equivalent to the original variable.

#### When transformations do not work

5

When none of the transformations results in homoscedasticity for the variables in the relationship, including that variable in the analysis will reduce our effectiveness at identifying statistical relationships, i.e. we lose power.

## Problem 1

In the dataset GSS2000.sav, is the following statement true, false, or an incorrect application of a statistic? Use 0.01 as the level of significance.

Based on a diagnostic hypothesis test for homogeneity of variance, the variance in "highest academic degree" is homogeneous for the categories of "marital status."

I. True

- 2. True with caution
- 3. False
- 4. Incorrect application of a statistic

#### Interpreting the homogeneity of variance test

Test of Homogeneity of Variances

RS HIGHES	ST DEGREE		
Levene <sup>39</sup>	4	262	,000
Statistic	df1	ЧŧS	Sia

The null hypothesis for the test of homogeneity of variance states that the variance of the dependent variable is equal across groups defined by the independent variable, i.e., the variance is homogeneous.

Since the probability associated with the Levene Statistic (<0.001) is less than or equal to the level of significance, we reject the null hypothesis and conclude that the variance is not homogeneous.

The answer to the question is false.

	the original number )	

#### Adding the variable name to the function

#### Preventing illegal logarithmic values

The log of zero is not defined mathematically. If we have zeros for the data values of some cases as we do for this variable, we add a constant to all cases so that no case will have a value of zero.

28

To solve this problem, we Compute Variable add + 1 to the degree variable in the function. Target Variable: Numeric Expression: LG10(degree + 1) logdegre =Type & Label... 🛞 childs 7 8 9 Functions: > 🏶 age 4 5 6 🗰 agekdbrn <= >= LAG(variable,ncases) 🗰 educ LENGTH(strexpr) 1 2 3 = LG10(numexpr) paeduc & 🗰 maeduc Click on the OK speduc button to complete 🛞 degree the compute request. #### The boxplot

30

In this boxplot, the spread is the same for 3 of the 5 groups, which is an improvement over the original boxplot.

However, it is difficult to judge whether or not the problem is solved based solely on the graphic.

#### The homogeneity of variance test

Test of Homogeneity of Variances

LOGDEGRE	=		
Leven51	4	262	.075
Statistic	Ч£1	ЧŧS	Sia

The null hypothesis for the test of homogeneity of variance states that the variance of the transformed dependent variable is equal across groups defined by the independent variable, i.e., the variance is homogeneous.

Since the probability associated with the Levene Statistic (0.075) is greater than the level of significance, we fail to reject the null hypothesis and conclude that the variance is homogeneous.

The answer to the question is true with caution.

## Homogeneity of variance test from the script

## Other problems on homoscedasticity assumption

33

- A problem may ask about the assumption of homoscedasticity for a nominal level <u>dependent</u> variable. The answer will be "An inappropriate application of a statistic" since variance is not computed for a nominal variable. Similarly, an ANOVA cannot be calculated if the <u>independent</u> variable is interval level and the answer will be "An inappropriate application of a statistic."
- A problem may ask about the assumption of homoscedasticity for an ordinal level <u>dependent</u> variable. If the variable or transformed variable satisfies the assumption of homogeneity of variance, the correct answer to the question is "True with caution" since we may be required to defend treating ordinal variables as metric.

#### Steps in answering questions about the assumption of homoscedasticity - question 1

34

The following is a guide to the decision process for answering problems about the homoscedasticity of a variable:
