

# The main types of nutrition in microorganisms

Learning Objective

### Identify the main types of nutrition in microorganisms

#### Success criteria

# 1.Analyse information about microbes and name them.

# 2.Name and identify correctly at least four types of nutrition.

#### Terminology

- bacteria, yeast, fungus, dose, continuous growth curve, a lag phase, an exponential / lag phase, stationary phase, a dead phase, monitors, viable cell microorganism, optical density, seeding
- Growth factor, Trace elements, Macronutritions, Nitrogen, carbohydrates, Hydrogen, Phosphorus, oxygen, Sulfur, Potassium, Calcium, glucose, carbon dioxide, water, pH, temperature, mineral ions
- •Nutrient supply, agar medium/growth medium, aeration
- Aseptic techniques, sterile, streak pattern

#### **Classification of <u>Nutrition</u> in Microoganisms**

*Carbon sources* – Autotrophs – CO2 sole or principal source <u>Heterotrophs</u> – reduced, preformed organic molecules

**Energy** sources

<u>Phototrophs</u> – light

<u>Chemotrophs</u> – oxidation of chemical compounds (organic/inorganic)

#### Electrons/Hydrogen sources

Lithotrophs – use reduced inorganic compounds as electron donors

<u>Organotrophs</u> – organic compounds/moleculs

"mixotrophs: they can alter their metabolic patterns in response to the particular environment. All bacteria require two things for growth:

#### 1) A source of energy

2) A source of matter for building additional cells: C, O, H, N, S, P, trace minerals.

#### **Nutrient Required for Growth**

<u>**Carbon**</u> – heterotrophs: glucose, fatty acids, alcohols, hydrocarbons...

<u>Nitrogen</u> – organic: amino acids, peptides, proteins

inorganic: ammonium salts and nitrates

<u>Water</u> – chemical reactions

<u>Growth factors, Vitamins, Mineral salts</u> – positive ions: calcium, potassium, sodium, B vitamins, some in TRACE (small) amounts

**Energy** – chemical or light

chemotrophs-chemical energy – glucose

phototrophic – light energy: blue green algae bacteria

### Elemental Assay of E. coli (dry weight)

- •50% carbon
- •20% oxygen
- •14% nitrogen
- •8% hydrogen
- •3% phosphorus
- •2% sulfur
- •2% potassium
- •0.05% calcium, magnesium, chlorine
- •0.2% iron
- •0.3% trace elements

#### Carbon

 the backbone of functional biological molecules: cells vary in their ability to synthesize all of their carbon compounds. Range of carbon compounds utilized: CO, CH4, to complex organic compounds.

#### Hydrogen

 structural molecule, participant in process of energy generation. Protons (H+) involved in ATP production, CO2 reduction, anaerobic and aerobic respiration.

#### Nitrogen

•in amino acids, nucleic acids. membranes, cell walls, and most macromolecules. Most free-living microbes assimilate ammonia from their environment or reduce nitrate. An array of microbial types can "fix" atmospheric nitrogen.

#### Sulfur

•in certain amino acids, some **B-vitamins (biotin and thiamine).** Reduced inorganic sulfur (e.g. H2S) used as energy source for thiobacilli. Sulfur serves as terminal electron acceptor in some Archaea.

#### Phosphorus

•a constituent of high energy compounds (ATP), phospholipids in membranes, nucleic acids.

#### Oxygen

 equal amounts in aerobes and anaerobes, but free oxygen toxic to anaerobes, so they obtain it in a combined form from the substrate.

### **Trace elements**, though not required in large amounts, are essential for cellular growth:

- K+ Principle cellular counterion
- Mg++ DNA polymerase
- Ca++ Intracellular signalling, wall structure
- Fe++ Cytochromes
- Mn++ PsII, photosynthesis
- Co++ Vitamin B12 constituent (methylations)
- Cu++ Superoxide dimutase
- Zn++ Some DNA binding proteins

#### **Organic Growth Factors**

•Organic Growth Factors are essential organic compounds that an organism is unable to synthesize. They must be obtained directly from the environment.

•Examples: Vitamins, Amino acids, Purines, pyrimidines

### Types of AGAR Media

### Liquid agar cultures of bacteria at the different stages of growth.

What the limiting factors a time = 4.5 – 5.5 hours?

What is happening to the culture at time =5.5-10 hours?

Serial Dilutions are used to reduce the number of bacterial colonies from liquid agar culture so they may be easily counted.

Calculation: Number of colonies on plate  $\times$  reciprocal of dilution of sample = number of bacteria/ml (For example, if 32 colonies are on a plate of <sup>1</sup>/10,000 dilution, then the count is 32  $\times$  10,000 = 320,000/ml in sample.)

#### Spectrophotomer or a colorimeter measures Used to measure 'turbidity' transmission of light

Light source Spectrophotometer Direct light 100 % Transmittance 0 % Absorbance 100 Percent light transmitted Light-sensitive Blank detector Scattered light 20 % Transmittance that does not reach detector 80 % Absorbance 1000 100 Percent light transmitted

Bacterial suspension

#### Turbidity – the cloudiness shows bacterial growth

Sterile Broth

Slight turbidity -some bacteria

Significant turbidity -lots of bacteria

Turbidity and Sediment -death phase – dead bacteria precipitate out of solution

Dead bacteria

Serial Dilutions are used to reduce the number of bacterial colonies from liquid agar culture so they may be easily counted.

Calculation: Number of colonies on plate  $\times$  reciprocal of dilution of sample = number of bacteria/ml (For example, if 32 colonies are on a plate of <sup>1</sup>/10,000 dilution, then the count is 32  $\times$  10,000 = 320,000/ml in sample.)

#### Practical: Plate it on different nutrient agar dishes

- 1- Nutrient closed petri dish
- 2- No nutrient closed petri dish
- 3- Glucose closed petri dish
- 4 No glucose closed petri dish
- 5 Nutrient open petri dish
- 6 No nutrient open petri dish

72 hours in incubator or 72 hours covered in warm part of room.

#### Success criteria

# 1.Analyse information about microbes and name them.

# 2.Name and identify correctly at least four types of nutrition.
