Collision Detection

Collisions

- Up to this point, objects just pass through each other
- Two parts to handling collisions
 - Collision detection uses computational geometry techniques (useful in other ways, too)
 - Collision response modifying physical simulation

Essential Math for

Comog

Computational Geometry

- Algorithms for solving geometric problems
- Object intersections
- Object proximity
- Path planning

Distance Testing

- Useful for computing intersection between simple objects
- E.g. sphere intersection boils down to point-point distance test
- Just cover a few examples

Point-Point Distance

• Compute length of vector between two points P_0 and P_1 , or

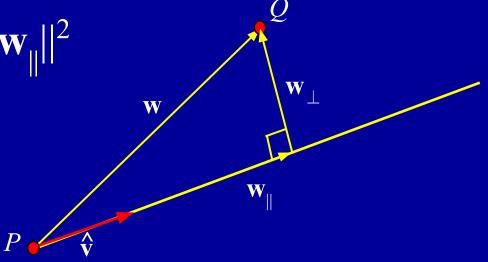

$$dist(P_0, P_1) = \sqrt{(x_0 - x_1)^2 + (y_0 - y_1)^2 + (z_0 - z_1)^2}$$

Line-Point Distance

- Line defined by point P and vector $\hat{\mathbf{v}}$
- Break vector $\mathbf{w} = Q P$ into \mathbf{w}_{\perp} and \mathbf{w}_{\parallel}

•
$$\mathbf{w}_{\parallel} = (\mathbf{w} \cdot \hat{\mathbf{v}}) \hat{\mathbf{v}}$$

•
$$||\mathbf{w}_{\perp}||^2 = ||\mathbf{w}||^2 - ||\mathbf{w}_{\parallel}||^2$$

Essential Math for

Gamas

Line-Point Distance

Final formula:

$$\operatorname{dist}(P, \hat{\mathbf{v}}, Q) = \sqrt{\mathbf{w} \bullet (\mathbf{w} - \hat{\mathbf{v}})}$$

If v isn't normalized:

$$dist(P, \mathbf{v}, Q) = \sqrt{\mathbf{w} \cdot \left(\mathbf{w} - \frac{\mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\right)}$$

Comog

Line-Line Distance

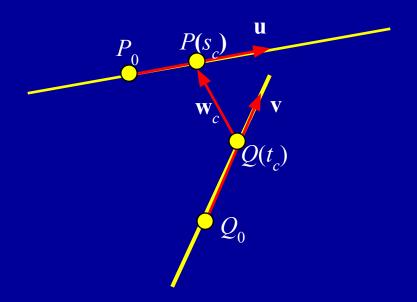

- From http://www.geometryalgorithms.com
- Vector \mathbf{w}_c perpendicular to \mathbf{u} and \mathbf{v} or

$$\mathbf{w}_c = P(s_c) - Q(t_c)$$

$$\mathbf{u} \bullet \mathbf{w}_c = 0$$

$$\mathbf{v} \bullet \mathbf{w}_c = 0$$

- Two equations
- Two unknowns

Essential Math for

Gamas

Line-Line Distance

Final equations:

$$P(s_c) = \mathbf{P}_0 + (be - cd)/(ac - b^2) \cdot \mathbf{u}$$

$$Q(t_c) = \mathbf{Q}_0 + (ae - bd)/(ac - b^2) \cdot \mathbf{v}$$

$$a = \mathbf{u} \cdot \mathbf{u}$$

$$b = \mathbf{u} \cdot \mathbf{v}$$

$$c = \mathbf{v} \cdot \mathbf{v}$$

$$d = \mathbf{u} \cdot (\mathbf{P}_0 - \mathbf{Q}_0)$$

$$e = \mathbf{v} \cdot (\mathbf{P}_0 - \mathbf{Q}_0)$$

Essential Math for

Gamas

Segment-Segment Distance

- Determine closest point between lines
- If lies on both segments, done
- Otherwise clamp against nearest endpoint and recompute
- See references for details

Essential Math for

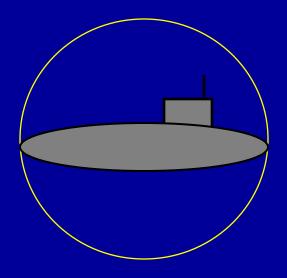

Comag

Bounding Objects

- Detecting intersections with complex objects expensive
- Provide simple object that surrounds them to cheaply cull out obvious cases
- Use for collision, rendering, picking
- Cover in increasing order of complexity

Bounding Sphere

- Tightest sphere that surrounds model
- For each point, compute distance from center, save max for radius

Essential Math for

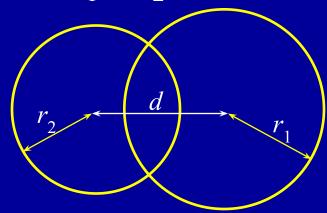

Camas

Bounding Sphere (Cont'd)

- What to use for center?
 - Local origin of model
 - Centroid (average of all points)
 - Center of bounding box
- Want a good fit to cull as much as possible
- Linear programming gives smallest fit

Sphere-Sphere Collision

- Compute distance d between centers
- If $d < r_1 + r_2$, colliding
- Note: d^2 is not necessarily $< r_1^2 + r_2^2$
 - want $d^2 < (r_1 + r_2)^2$

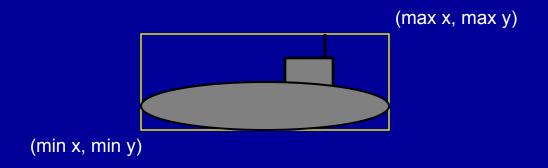

Essential Math for

Gamas

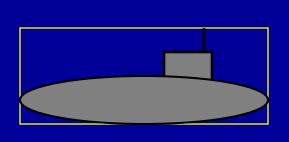

Bounding Box

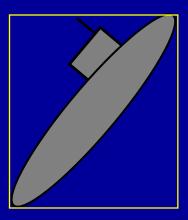

- Tightest box that surrounds model
- Compare points to min/max vertices
- If element less/greater, set element in min/max

Axis-Aligned Bounding Box

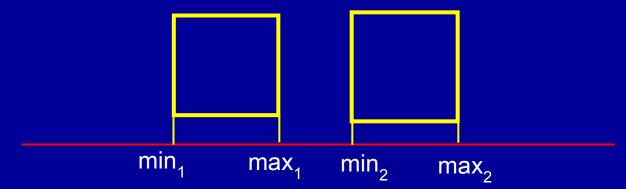

- Box edges aligned to world axes
- Recalc when object changes orientation
- Collision checks are cheaper though

Axis-Aligned Box-Box Collision

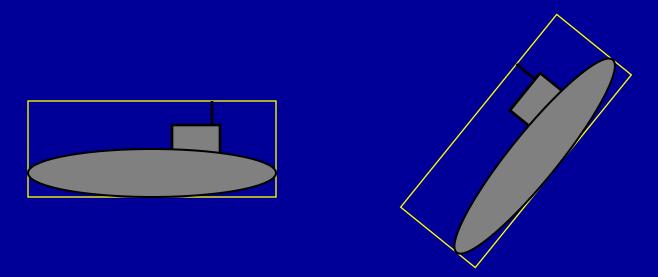

- Compare x values in min, max vertices
- If min₂ > max₁ or min₁ > max₂, no collision (separating plane)

Otherwise check y and z directions

Object-Oriented Bounding Box

- Box edges aligned with local object coordinate system
- Much tighter, but collision calcs costly

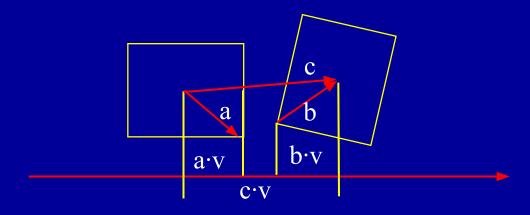

Essential Math for

Camaa

OBB Collision

- Idea: determine if separating plane between boxes exists
- Project box extent onto plane vector, test against projection btwn centers

Essential Math for

Comas

OBB Collision

 To ensure maximum extents, take dot product using only absolute values

$$|a_x v_x| + |a_y v_y| + |a_z v_z|$$

- Check against axes for both boxes, plus cross products of all axes
- See Gottschalk for more details

Capsule

- Cylinder with hemispheres on ends
- One way to compute
 - Calc bounding box
 - Use long axis for length
 - Next largest width for radius

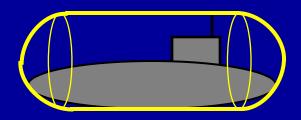

Essential Math for

Camas

Capsule

- Compact
 - Only store radius, endpoints of line segment
- Oriented shape w/faster test than OBB
- Test path collision

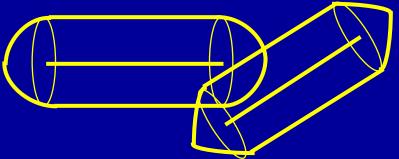

Essential Math for

Comag

Capsule-Capsule Collision

- Key: swept sphere axis is line segment with surrounding radius
- Compute distance between line segments
- If less than $r_1 + r_2$, collide

Essential Math for

Gamas

Caveat

- Math assumes infinite precision
- Floating point is not to be trusted
- Precision worse farther from 0
- Use epsilons
- Careful of operation order
- Re-use computed results
- More on floating point on website

Essential Math for

Gamas

Which To Use?

- As many as necessary
- Start with cheap tests, move up the list
 - Sphere
 - Swept Sphere
 - Box
- May not need them all

Recap

- Sphere -- cheap, not a good fit
- AABB -- still cheap, but must recalc and not a tight fit
- Swept Sphere -- oriented, cheaper than
 OBB but generally not as good a fit
- OBB -- somewhat costly, but a better fit

Collision Detection

- Naïve: n^2 checks!
- Two part process
 - Broad phase
 - Cull out non-colliding pairs
 - Narrow phase
 - Determine penetration and contact points between pairs

Essential Math for

Gamas

Broad Phase

- Obvious steps
 - Only check each pair once
 - Flag object if collisions already checked
 - Only check moving objects
 - Check against other moving and static
 - Check rough bounding object first
 - AABB or sphere

Essential Math for

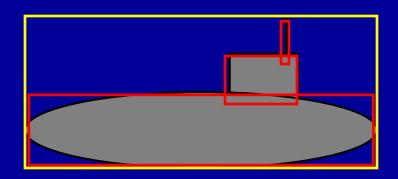

Comog

Hierarchical Systems

- Can break model into hierarchy and build bounds for each level of hierarchy
- Finer level of detection
- Test top level, cull out lots of lower levels

Hierarchical Systems

- Can use scene graph to maintain bounding information
- Propagate transforms down to children
- Propagate bound changes up to root

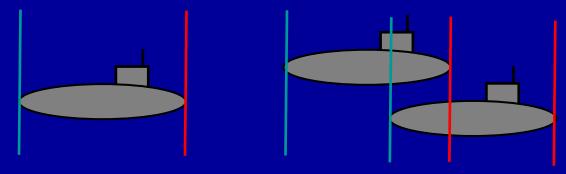

Spatial Subdivision

- Break world into separate areas
- Only check your area and neighbors
- Simplest: uniform
 - Slabs
 - Grid
 - Voxels

Sweep and Prune

- Store sorted x extents of objects
- Sweep from min x to max x
- As object min value comes up, make active, test against active objects
- Can extend to more dimensions

Essential Math for

Gamag

Spatial Subdivision

- Other methods:
 - Quadtrees, octrees
 - BSP trees, kd-trees
 - Room-portal
- Choice depends on your game type, rendering engine, memory available, etc.

Temporal Coherence

- Objects nearby generally stay nearby
- Check those first
- Can take memory to store information

Narrow Phase

- Have culled object pairs
- Need to find
 - Contact point
 - Normal
 - Penetration (if any)

Contact Region

 Two objects interpenetrate, have one (or more) regions

Many try to avoid interpenetration

Contact Features

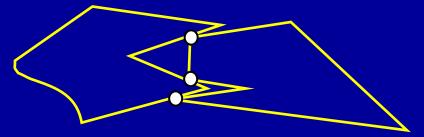

- Faceted objects collide at pair of contact features
- Only consider E-E and F-V pairs
- Infinite possibilities for normals for others
- Can generally convert to E-E and F-V
- Ex: V-V, pick neighboring face for one

Contact Features

- For E-E:
 - Point is intersection of edges
 - Normal is cross product of edge vectors
- For F-V:
 - Point is vertex location
 - Normal is face normal

Contact Points

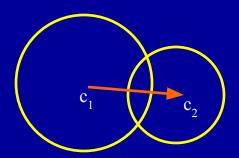

- Can have multiple contact points
 - Ex: two concave objects

- Store as part of collision detection
- Collate as part of collision resolution

Example: Spheres

 Difference between centers gives normal n (after you normalize)

• Penetration distance p is $(r_1+r_2) - \|\mathbf{c}_2-\mathbf{c}_1\|$

$$p =$$

Example: Spheres

Collision point: average of penetration distance along extended normal

$$\mathbf{v} = \frac{1}{2}(\mathbf{c}_1 + r_1\hat{\mathbf{n}} + \mathbf{c}_2 - r_2\hat{\mathbf{n}})$$

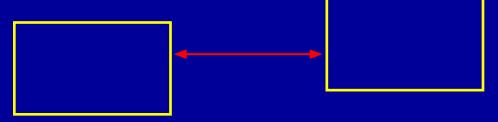

• If touching, where normal crosses sphere

Lin-Canny

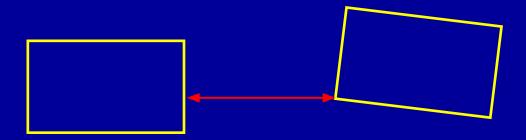

- For convex objects
- Easy to understand, hard to implement
- Closest features generally same from frame to frame
- Track between frames
- Modify by walking along object

Lin-Canny

• Frame 0

Frame 1

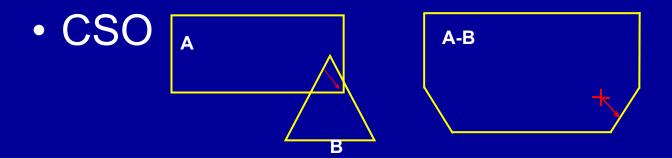

Essential Math for

Gamag

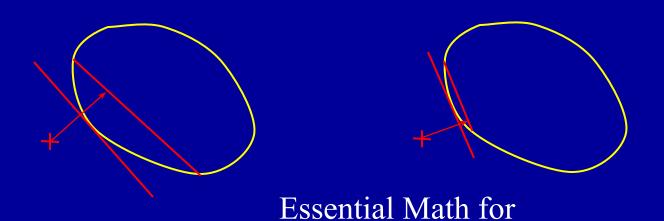

GJK

- For Convex Objects
- Hard to understand, easy to implement
- Finds point in Configuration Space
 Obstacle closest to origin. Corresponds
 to contact point
- Iteratively finds points by successive refinement of simplices

GJK

Simplex Refinement

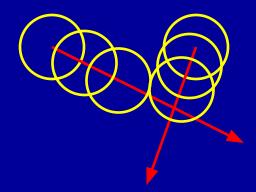

Comoa

Missing Collision

 If time step is too large for object speed, two objects may pass right through each other without being detected (tunneling)

Missing Collision

- One solution: slice time interval
- Simulate between slices

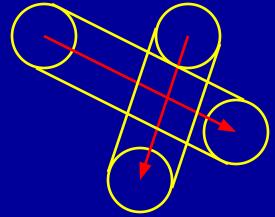

Same problem, just reduced frequency

Essential Math for

Gamag

Missing Collision

Another solution: use swept volumes

- If volumes collide, may collide in frame
- With more work can determine time-of-impact (TOI), if any

Recap

- Collision detection complex
- Combo of math and computing
- Break into two phases: broad and narrow
- Be careful of tunneling
