Cryptography and Network Security Chapter 5

#### Fifth Edition by William Stallings

Lecture slides by Lawrie Brown

#### Chapter 5 – Advanced Encryption Standard

"It seems very simple." "It is very simple. But if you don't know what the key is it's virtually indecipherable." —Talking to Strange Men, Ruth Rendell

## **AES** Origins

- clear a replacement for DES was needed
  - have theoretical attacks that can break it
  - have demonstrated exhaustive key search attacks
- □ can use Triple-DES but slow, has small blocks
- US NIST issued call for ciphers in 1997
- 15 candidates accepted in Jun 98
- □ 5 were shortlisted in Aug-99
- Rijndael was selected as the AES in Oct-2000
   issued as FIPS PUB 197 standard in Nov-2001

# The AES Cipher - Rijndael

- designed by Rijmen-Daemen in Belgium
- has 128/192/256 bit keys, 128 bit data
- an iterative rather than Feistel cipher
  - processes data as block of 4 columns of 4 bytes
  - operates on entire data block in every round

#### designed to have:

- resistance against known attacks
- speed and code compactness on many CPUs
- design simplicity

## AES Encryption Process

6

#### **AES Structure**

- data block of 4 columns of 4 bytes is state
- key is expanded to array of words
- has 9/11/13 rounds in which state undergoes:
  - byte substitution (1 S-box used on every byte)
  - shift rows (permute bytes between groups/columns)
  - mix columns (subs using matrix multiply of groups)
  - add round key (XOR state with key material)

view as alternating XOR key & scramble data bytes
initial XOR key material & incomplete last round
with fast XOR & table lookup implementation

#### **AES Structure**

## **Some Comments on AES**

- 1. an iterative rather than Feistel cipher
- 2. key expanded into array of 32-bit words
  - four words form round key in each round
- 3. 4 different stages are used as shown
- 4. has a simple structure
- 5. only AddRoundKey uses key
- 6. AddRoundKey a form of Vernam cipher
- 7. each stage is easily reversible
- 8. decryption uses keys in reverse order
- 9. decryption does recover plaintext
- 10. final round has only 3 stages

## **Substitute Bytes**

- a simple substitution of each byte
- uses one table of 16x16 bytes containing a permutation of all 256 8-bit values
- each byte of state is replaced by byte indexed by row (left 4-bits) & column (right 4-bits)
  - eg. byte {95} is replaced by byte in row 9 column 5
  - which has value {2A}
- S-box constructed using defined transformation of values in GF(2<sup>8</sup>)
- designed to be resistant to all known attacks

### **Substitute Bytes**

#### Substitute Bytes Example

EA	04	65	85		87	F2	4D	97
83	45	5D	96	-	EC	6E	4C	90
5C	33	98	<b>B</b> 0		4A	C3	46	E7
F0	2D	AD	C5		8C	D8	95	A6

## **Shift Rows**

- a circular byte shift in each each
  - 1<sup>st</sup> row is unchanged
  - 2<sup>nd</sup> row does 1 byte circular shift to left
  - 3rd row does 2 byte circular shift to left
  - 4th row does 3 byte circular shift to left

decrypt inverts using shifts to right
 since state is processed by columns, this step permutes bytes between the columns

#### Shift Rows

87	F2	4D	97		87	F2	4D	97
EC	6E	4C	90	-	6E	4C	90	EC
4A	C3	46	E7		46	E7	4A	C3
8C	D8	95	A6		A6	8C	D8	95

#### **Mix Columns**

 each column is processed separately
 each byte is replaced by a value dependent on all 4 bytes in the column
 effectively a matrix multiplication in GF(2<sup>8</sup>) using prime poly m(x) =x<sup>8</sup>+x<sup>4</sup>+x<sup>3</sup>+x+1

[02	03	01	01]	S0,0	S0,1	s <sub>0,2</sub>	50,3	1	[s0.0	s'0,1	S0.2	s <sub>03</sub> ]
01	02	03	01	s <sub>1,0</sub>	s <sub>1,1</sub>	s <sub>1,2</sub>	s <sub>1,3</sub>		s'1,0	\$1,1	\$1,2	s'1,3
01	01	02	03	\$2,0	s <sub>2,1</sub>	s <sub>2,2</sub>	s2,3	=	s2,0	\$2,1	s2,2	\$2.3
03	01	01	02	\$3,0	\$3,1	s <sub>3,2</sub>	S3,3		\$3,0	\$3,1	\$3,2	\$3,3

#### **Mix Columns**

#### Mix Columns Example

87	F2	4D	97		47	40	A3	4C
6E	4C	90	EC		37	D4	70	9F
46	E7	4A	C3	-	94	E4	3A	42
A6	8C	D8	95		ED	A5	A6	BC

({02} • {87})	⊕ ({03} • {6E })	⊕ {46}	⊕ {A6}	= {47}
{87}	$\oplus ({02} \cdot {6E})$	$\oplus$ ({03} • {46})	⊕ {A6}	= {37}
{87}	⊕ {6E }	$\oplus$ ({02} • {46})	⊕ ({03} • { A6})	= {94}
({03} • {87})	⊕ {6E }	⊕ {46}	⊕ ({02} • { A6})	= {ED}

## **AES Arithmetic**

uses arithmetic in the finite field GF(2<sup>8</sup>)
 with irreducible polynomial

 m(x) = x<sup>8</sup> + x<sup>4</sup> + x<sup>3</sup> + x + 1

which is (100011011) or {11b}

e.g.
{02} • {87} mod {11b} = (1 0000 1110) mod {11b}
= (1 0000 1110) xor (1 0001 1011) = (0001 0101)

### Mix Columns

- can express each col as 4 equations
  - to derive each new byte in col
- decryption requires use of inverse matrix
  - with larger coefficients, hence a little harder
- have an alternate characterisation
  - each column a 4-term polynomial
  - with coefficients in GF(2<sup>8</sup>)
  - and polynomials multiplied modulo (x<sup>4</sup>+1)

coefficients based on linear code with maximal distance between codewords

## Add Round Key

XOR state with 128-bits of the round key again processed by column (though) effectively a series of byte operations) inverse for decryption identical since XOR own inverse, with reversed keys designed to be as simple as possible a form of Vernam cipher on expanded key requires other stages for complexity / security

## Add Round Key

#### **AES Round**

 $\bigcirc$ 

## **AES Key Expansion**

- takes 128-bit (16-byte) key and expands into array of 44/52/60 32-bit words
  start by copying key into first 4 words
  then loop creating words that depend on values in previous & 4 places back
  in 3 of 4 cases just XOR these together
  - 1<sup>st</sup> word in 4 has rotate + S-box + XOR round constant on previous, before XOR 4<sup>th</sup> back

## **AES Key Expansion**

## **Key Expansion Rationale**

- designed to resist known attacks
- design criteria included
  - knowing part key insufficient to find many more
  - invertible transformation
  - fast on wide range of CPU's
  - use round constants to break symmetry
  - diffuse key bits into round keys
  - enough non-linearity to hinder analysis
  - simplicity of description

## **AES Decryption**

- AES decryption is not identical to encryption since steps done in reverse but can define an equivalent inverse cipher with steps as for encryption but using inverses of each step • with a different key schedule works since result is unchanged when swap byte substitution & shift rows
  - swap mix columns & add (tweaked) round key

## **AES Decryption**

## **Implementation Aspects**

- can efficiently implement on 8-bit CPU
  - byte substitution works on bytes using a table of 256 entries
  - shift rows is simple byte shift
  - add round key works on byte XOR's
  - mix columns requires matrix multiply in GF(2<sup>8</sup>) which works on byte values, can be simplified to use table lookups & byte XOR's

#### Implementation Aspects

can efficiently implement on 32-bit CPU

- redefine steps to use 32-bit words
- can precompute 4 tables of 256-words
- then each column in each round can be computed using 4 table lookups + 4 XORs
  at a cost of 4Kb to store tables

designers believe this very efficient implementation was a key factor in its selection as the AES cipher

## Summary

have considered:

- the AES selection process
- the details of Rijndael the AES cipher
- looked at the steps in each round
- the key expansion
- implementation aspects
